INSPECTION OF WEIGHTS AND MEASURES, GAS AND ELECTRIC LIGHT

PRINTED BY ORDER OF PARLIAMENT

OTTAWA
PRINTED BY S. E. DAWSON, PRINTER TO THE KING'S MOST EXCELLENT MAJESTY
1901

[No. 13—1902.]

REPORT

OF THE

DEPUTY MINISTER OF INLAND REVENUE

ON THE

INSPECTION OF WEIGHTS AND MEASURES, GAS AND ELECTRIC LIGHT

To the Honourable
The Minister of Inland Revenue.

SIR,—I have the honour to submit herewith my annual report on the inspection of weights and measures, gas and electric light, with the usual statements in connection therewith, for the fiscal year ended June 30, 1901.

1. The total revenue collected during the year for the inspection of weights and measures was $54,385.56, as against $53,635.04 collected during the year ended June 30, 1900.

2. The total expenditure was $71,280.37, as against $68,707.55 expended during the year ended June 30, 1900.

3. Appendix 'A' gives a summary statement of the receipts and expenditures of each inspection division.

4. In Appendices 'B,' 'C' and 'D' will be found a detailed statement of weights, measures and weighing machines presented for verification verified and rejected during the year. The number of all descriptions may be summarily stated as follows:—

—	Presented.	Verified.	Rejected.	Percentage of Rejections.
Weights, Dominion	62,281	61,553	728	1·16
Measures of capacity, Dominion	84,327	84,205	122	0·14
Lineal measures	7,122	6,978	144	2·02
Balances, equal arms	12,089	11,784	305	2·52
" steelyards	4,654	4,520	134	2·87
" platform scales	31,000	29,964	1,036	3·34
Troy weights	67	67	.....	.....
Irregular weights	687	685	2	·29
" measures	488	486	2	·40
" balances	5,876	5,688	188	3·20

INSPECTION OF GAS.

5. The total revenue collected during the fiscal year ended June 30, 1901, for the inspection of gas and gas meters, was $22,173.55, as compared with $21,106.75 collected during the year ended June 30, 1900.

6. The total expenses were $23,338.49, as against $22,706.16 expended during the year ended June 30, 1900.

7. Appendix 'E' gives a summary statement of the receipts and expenditures of each gas inspection district.

8. A statement of the illuminating power and purity of gas inspected during the year will be found in Appendix 'F.'

9. The illuminating power, where inspection has been made, has been as follows:—

Places.	Number of Tests made.	Number of times below Standard.	Places.	Number of Tests made.	Number of times below Standard.
Barrie	12		Sarnia	12	
Belleville	34		Stratford	12	1
Berlin	12		St. Catharines	12	
Brantford	12		St. Thomas	14	
Brockville	12		Toronto	104	
Chatham	12		Windsor	13	1
Cobourg	12		Woodstock	12	
Cornwall	12		Montreal	102	
Deseronto	8		Quebec	12	
Dundas	12		Sherbrooke	12	2
Galt	12		Fredericton	55	1
Guelph	12		Moncton	9	
Hamilton	12		St. John, N.B	47	1
Ingersoll	12		Halifax	12	
Kingston	22		Pictou	10	
Listowell	12		Yarmouth	10	
London	19		Charlottetown	12	
Napanee	10		Winnipeg	12	
Ottawa	24		Nanaimo	12	
Owen Sound	12		New Westminster		
Peterborough	12		Vancouver	12	
Port Hope	12		Victoria	11	

The revenue derived from the inspection of electric light was as follows :—

Fees for inspection of meters, &c	$ 10,565 52
Registration of companies	4,797 50
	$ 15,363 02
The expenses of inspection (annual)	4,908 71
	$ 10,454 31
Expended on standard instruments, &c	4,199 26
Leaving a net revenue of	$ 6,255 05

Appendix 'K' contains extracts from a paper on Dominion Electrical Standards read before the Canadian Electrical Association by Mr. O. Higman, Chief Electrical Engineer of the Department, on June 20, 1901.

Since the year 1896–97 the two services of gas and electric light inspection, which are conducted largely by the same staff of officers, have reached that point at which they have ceased to be a burden upon the general taxpayer, as shown below :—

Year.	Gas and Electric Light.	
	Revenue.	Expenditure, Exclusive of cost of Standard Instruments.
	$ cts.	$ cts.
1897–98	28,150 00	23,402 00
1898–99	30,015 25	23,436 30
1899–1900	35,523 50	26,424 48
1900–01	37,536 57	28,247 20

The kindred service of weights and measures inspection, it will be observed, has, the same as last year, earned somewhat over three-fourths of its annual cost, the expenditure as already stated having been $71,280.37, against a revenue of $54,385.56.

Owing to the adoption, by many of the leading nations of the world, of the 'Metric System' of weights and measures, and in order that the people of our country might become conversant therewith, the department has distributed to Boards of Trade and Educational Institutions throughout the Dominion, over one hundred sample sets of Metric Weights and Measures. It has also recently procured standards which will be placed in the hands of Inspectors at the leading Commerical centres, by means of which weights of the Metrical System may, when required, be verified.

These standard sets contain the following weights, viz.:—20, 10, 5, 2, (2). Kilogrammes, I Kilogramme, 500, 200, (2). 100, 50, 20 (2). 10, 5, 2, (2). Grammes, 1 gramme, 5, 2, (2). Decigrammes, I decigramme, 5, 2, (2). Centigrammes, I Centigramme, 5, 2, (2). Milligrammes, I Milligramme.

I have the honour to be, sir,

Your obedient servant,

W. J. GERALD,

Deputy Minister.

Inland Revenue Dept.,

Ottawa, August 10, 1901.

INLAND REVENUE DEPARTMENT,
OTTAWA, August 10, 1901.

W. J. GERALD,
Deputy Minister.

DOMINION ELECTRICAL STANDARDS

BY

ORMOND HIGMAN, M. INST. E. E.; A. M. CAN. SOC. C. E.,

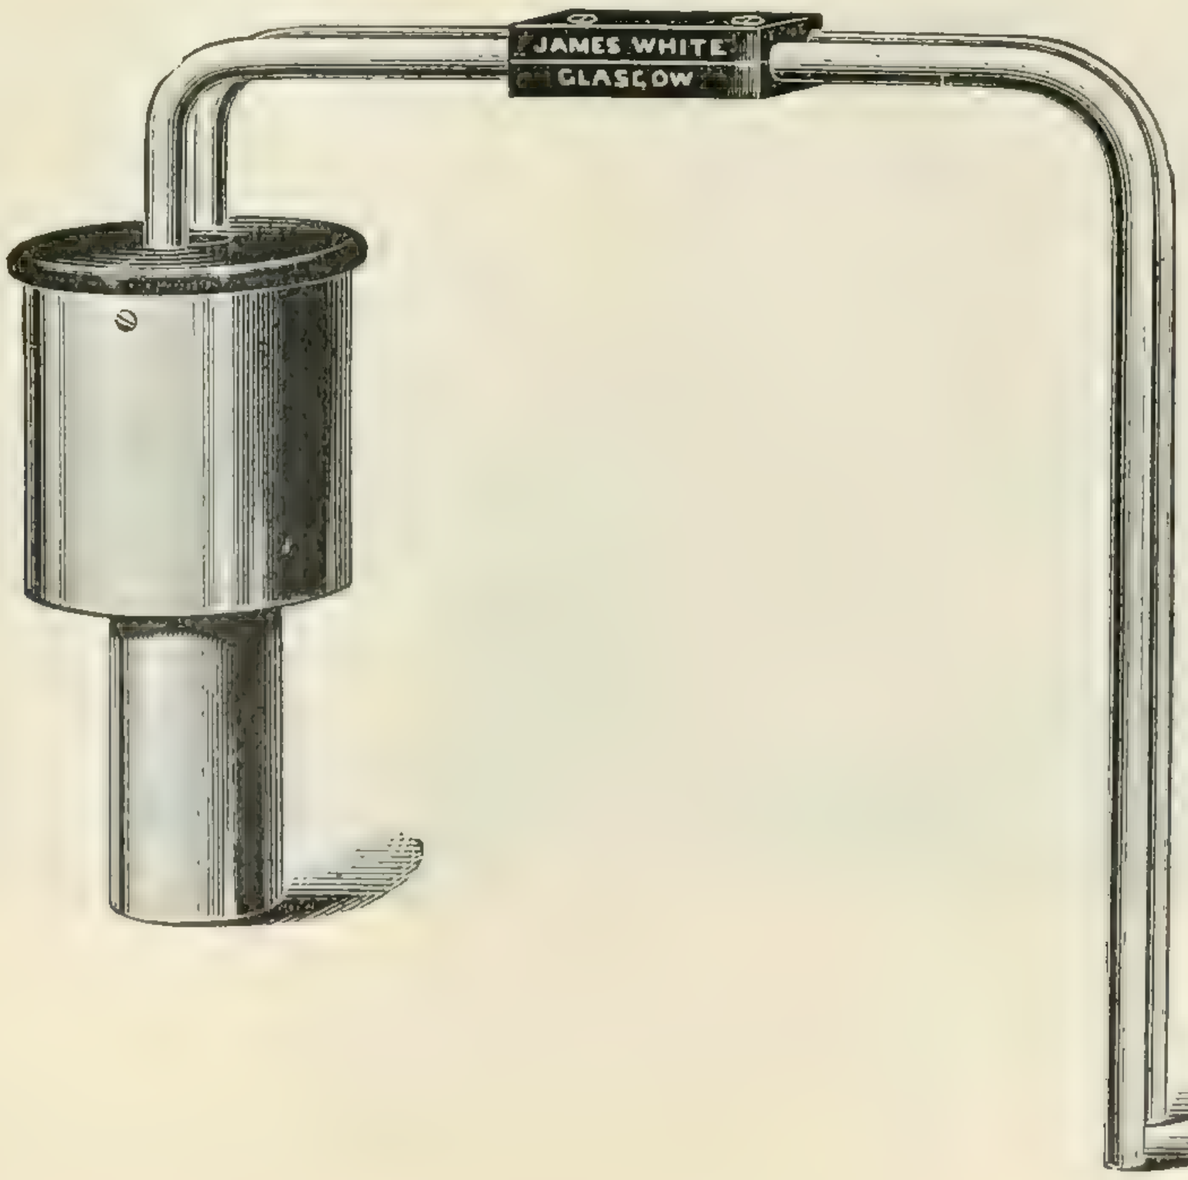
Chief Electrical Engineer, Inland Revenue Department.

In 1894 when Parliament passed the Electrical Units Act, (Schedule A.) the writer was called upon to procure the apparatus necessary to produce and express the standard units therein legalized.

In seeking for guidance in the discharge of this important and responsible duty, I naturally turned to the brilliant work accomplished by the Committee on Electrical Standards appointed by the British Association in the seventies, and the no less brilliant work accomplished by the Electrical Standards Committee of the Board of Trade and contained in their report to Parliament in 1891-92. The results of the labours of these committees will, I venture to say, be found to be the most interesting and instructive chapters in the history of electrical science. At the period when they commenced their labours the experimental sciences of electricity and magnetism were, for the most part, mere collections of qualitative results estimated by means of units which were altogether arbitrary. The work of the committees changed experimental electricity into an exact science by adopting the C. G. S. system as their fundamental basis, and which enabled them to express their results in units that are altogether independent of instruments or surroundings. For practical purposes, however, it was necessary that the units should find expression in apparatus, the accuracy and constancy of which could not be questioned. For the absolute measurement of current and electro-motive force, both varying and unvarying, Lord Kelvin's instruments were recommended. The following apparatus has been procured by the department as Standards of Electrical measure; and although not by any means complete, I am glad to be able to report that substantial progress has been made in complying with the requirements of section 3 of the Units Act.

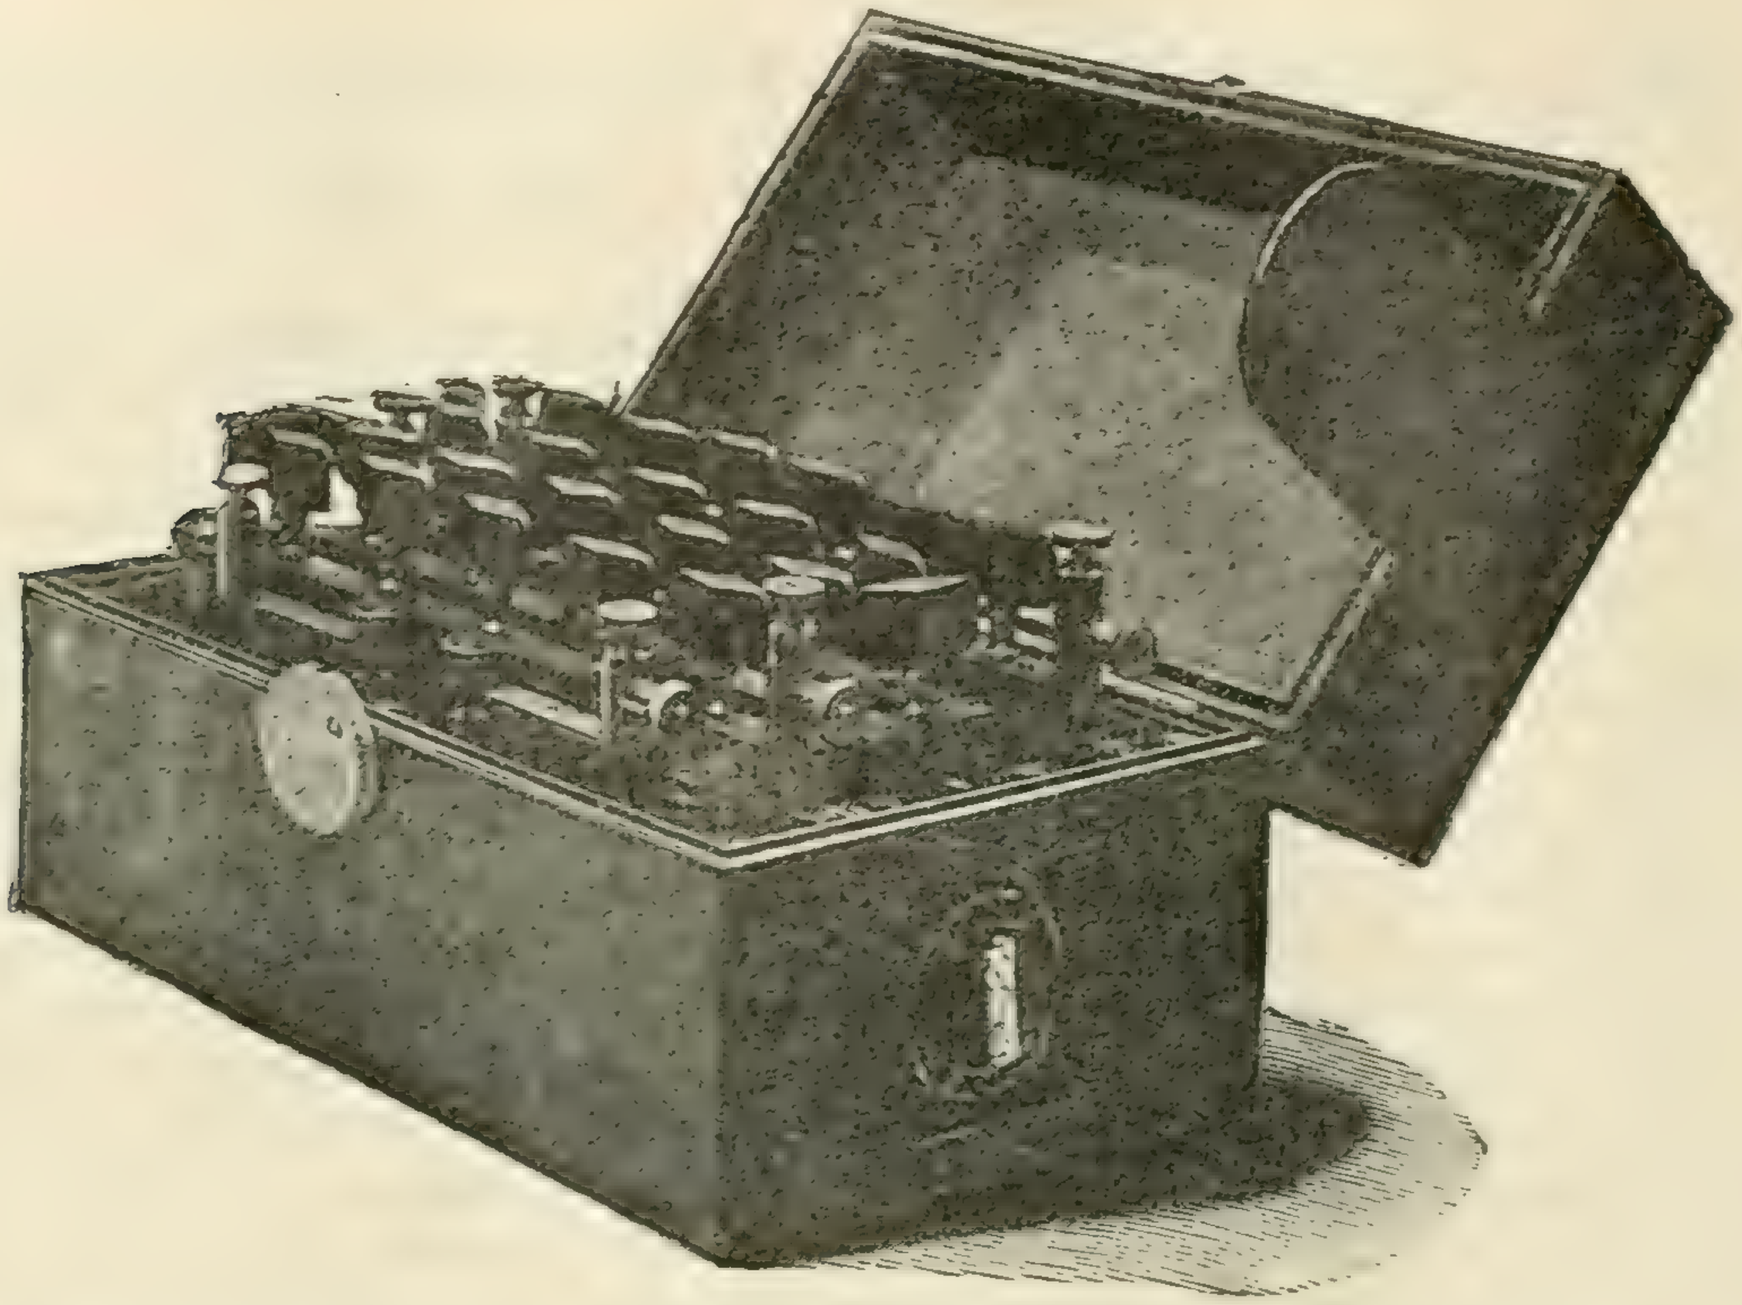
STANDARDS OF RESISTANCE.

Two standard ohms, one of the Board of Trade and one of the Reichsanstalt (Berlin) pattern.

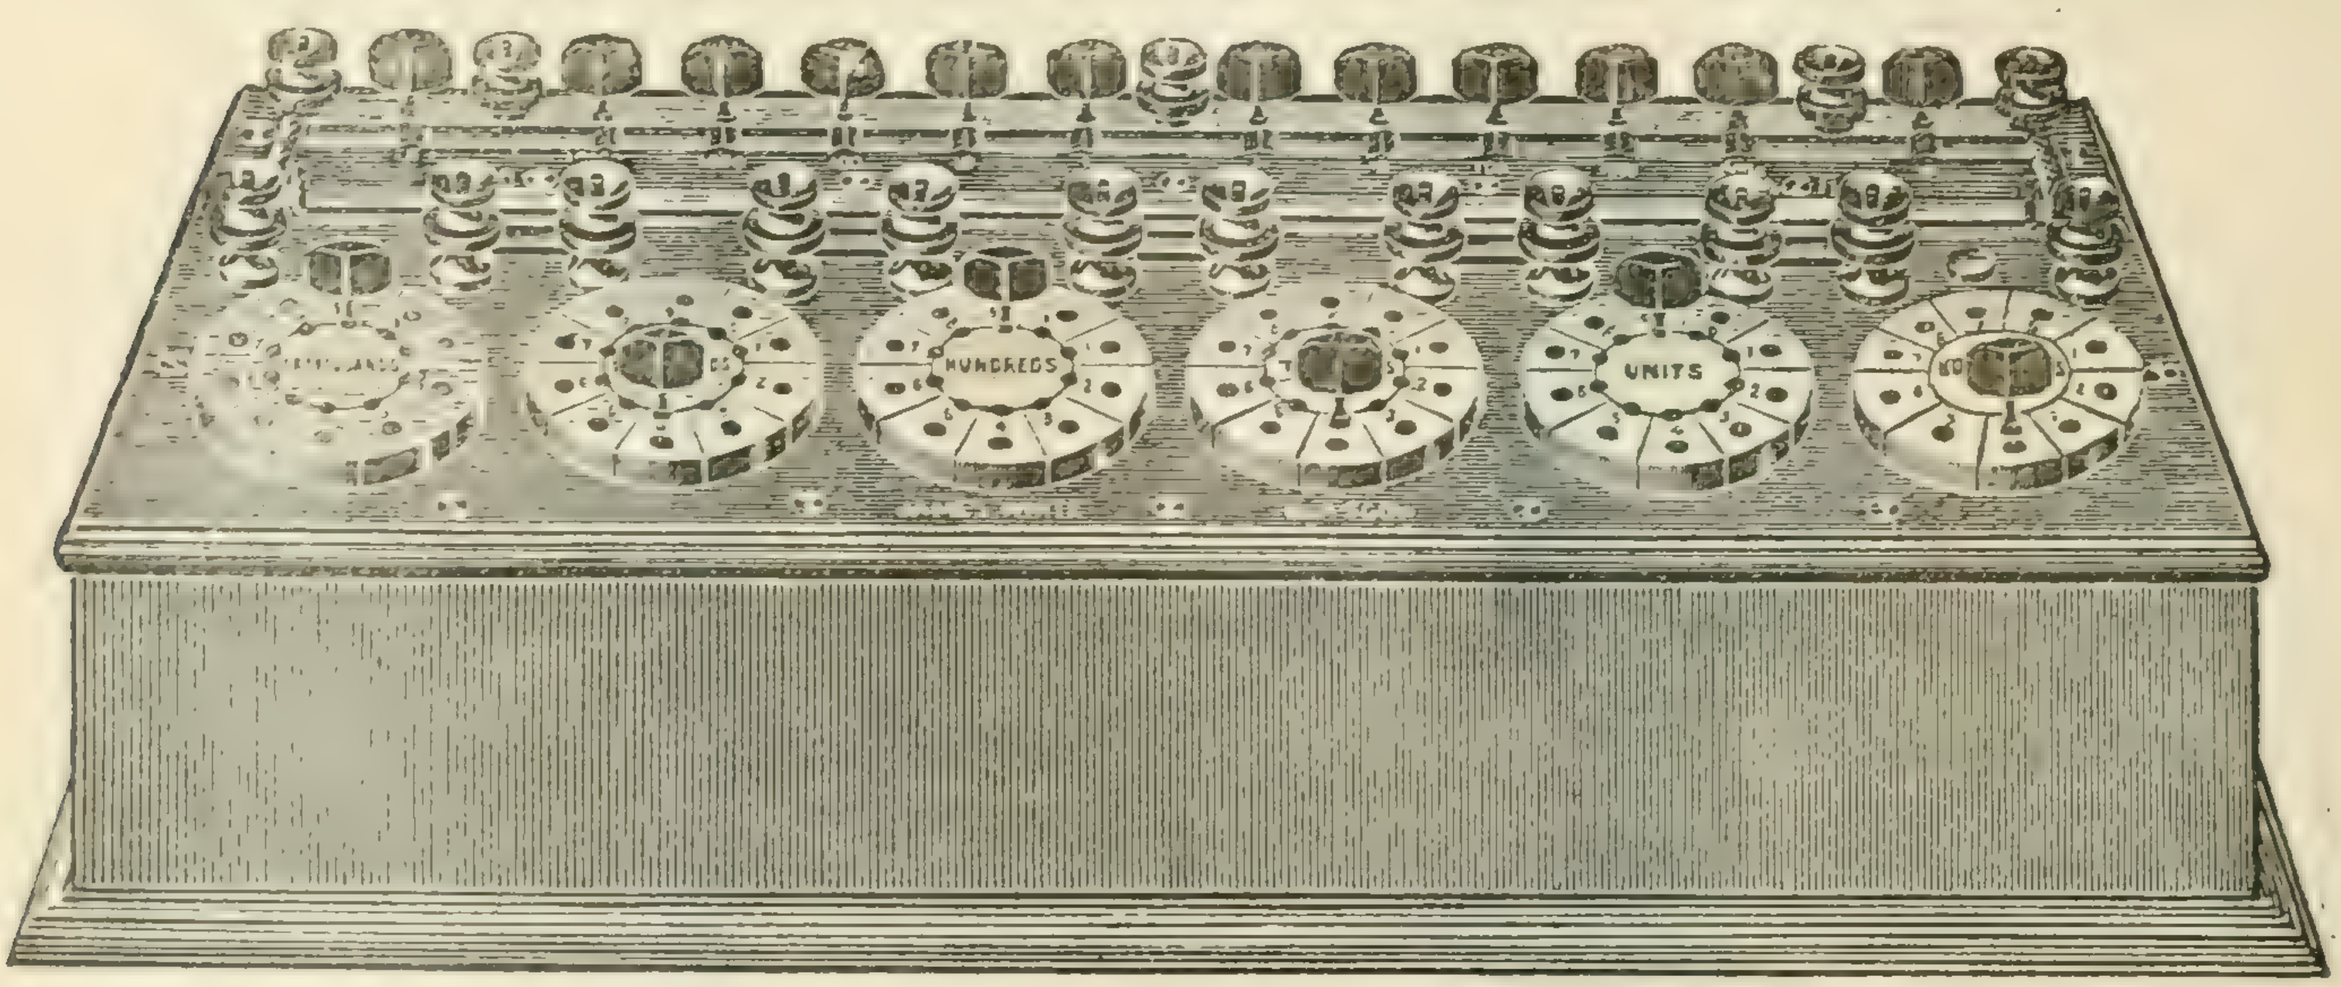


One resistance box containing ten 1 ohm coils with suitable plugging arrangements for putting the coils in series as a 10 ohm standard or in multiple as a $\frac{1}{10}$ ohm standard.

One Kelvin resistance coil 100,000 ohms with 10 sub-divisions of 10,000 ohms, each arranged with plugs for connecting in series or in parallel or any combination of series and parallel.



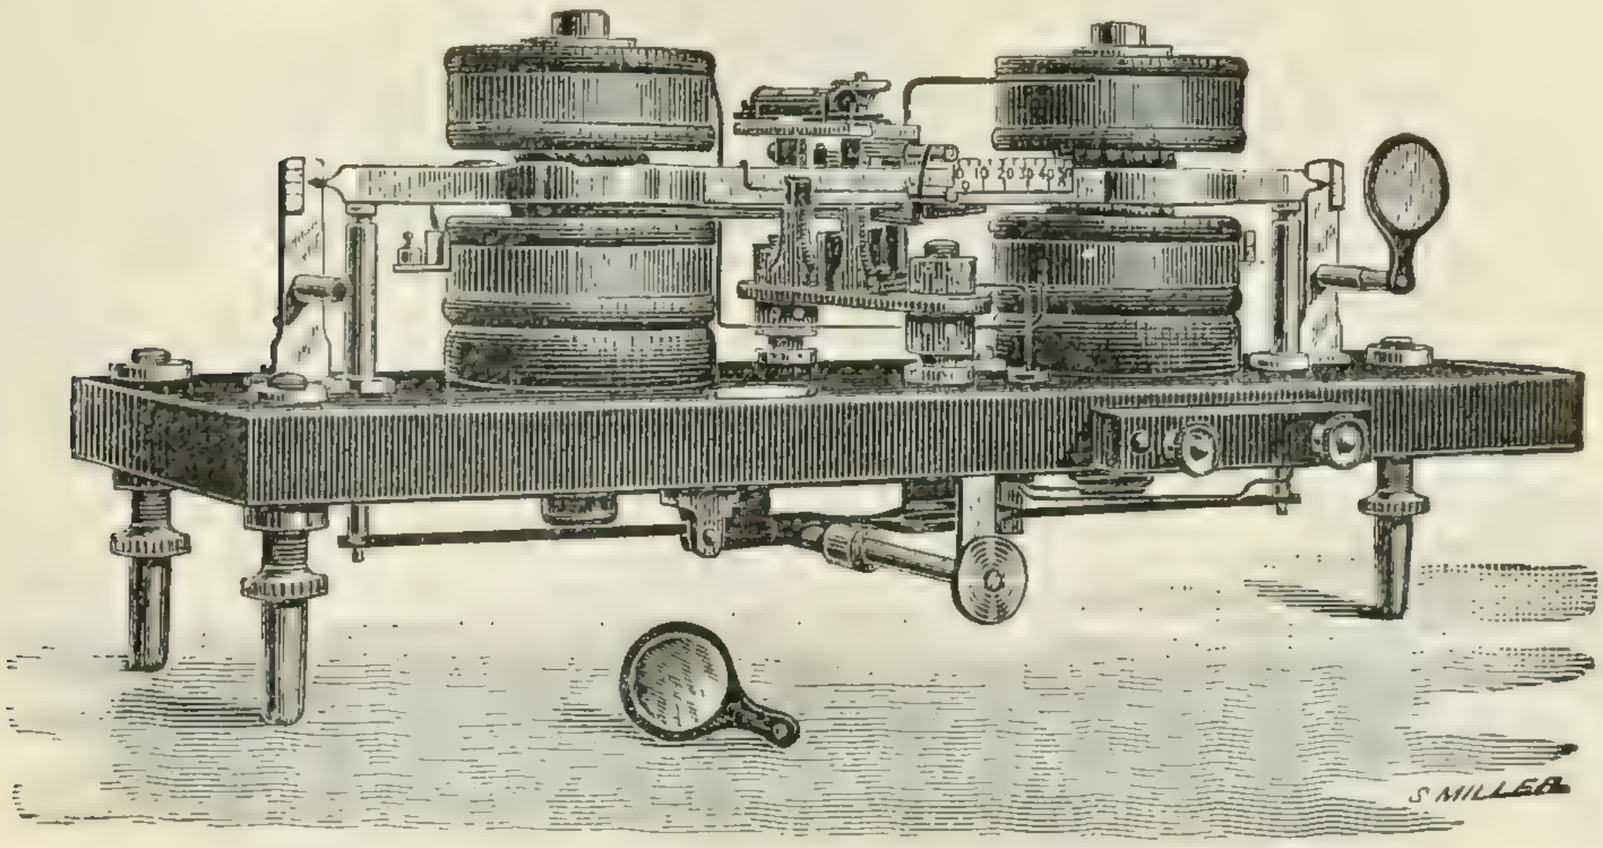
One Wheatstone Bridge (Anthony pattern) with ratio coils 1, 10, 100, 1,000 and 10,000 on each side with bridge coils of tenths, units, tens, hundreds and thousands. These coils are made of manganin wire specially selected and the box is fitted with an electric thermometer. Measurements of great accuracy can be obtajned with this bridge used in conjunction with a sensitive reflecting D'Arsonval galvanometer. Intercomparisons between these standards will be made from time to time and records kept of their variations.



MEASUREMENT OF CURRENT.

For the measurement of current a set of Lord Kelvin's balances has been provided covering the following ranges:

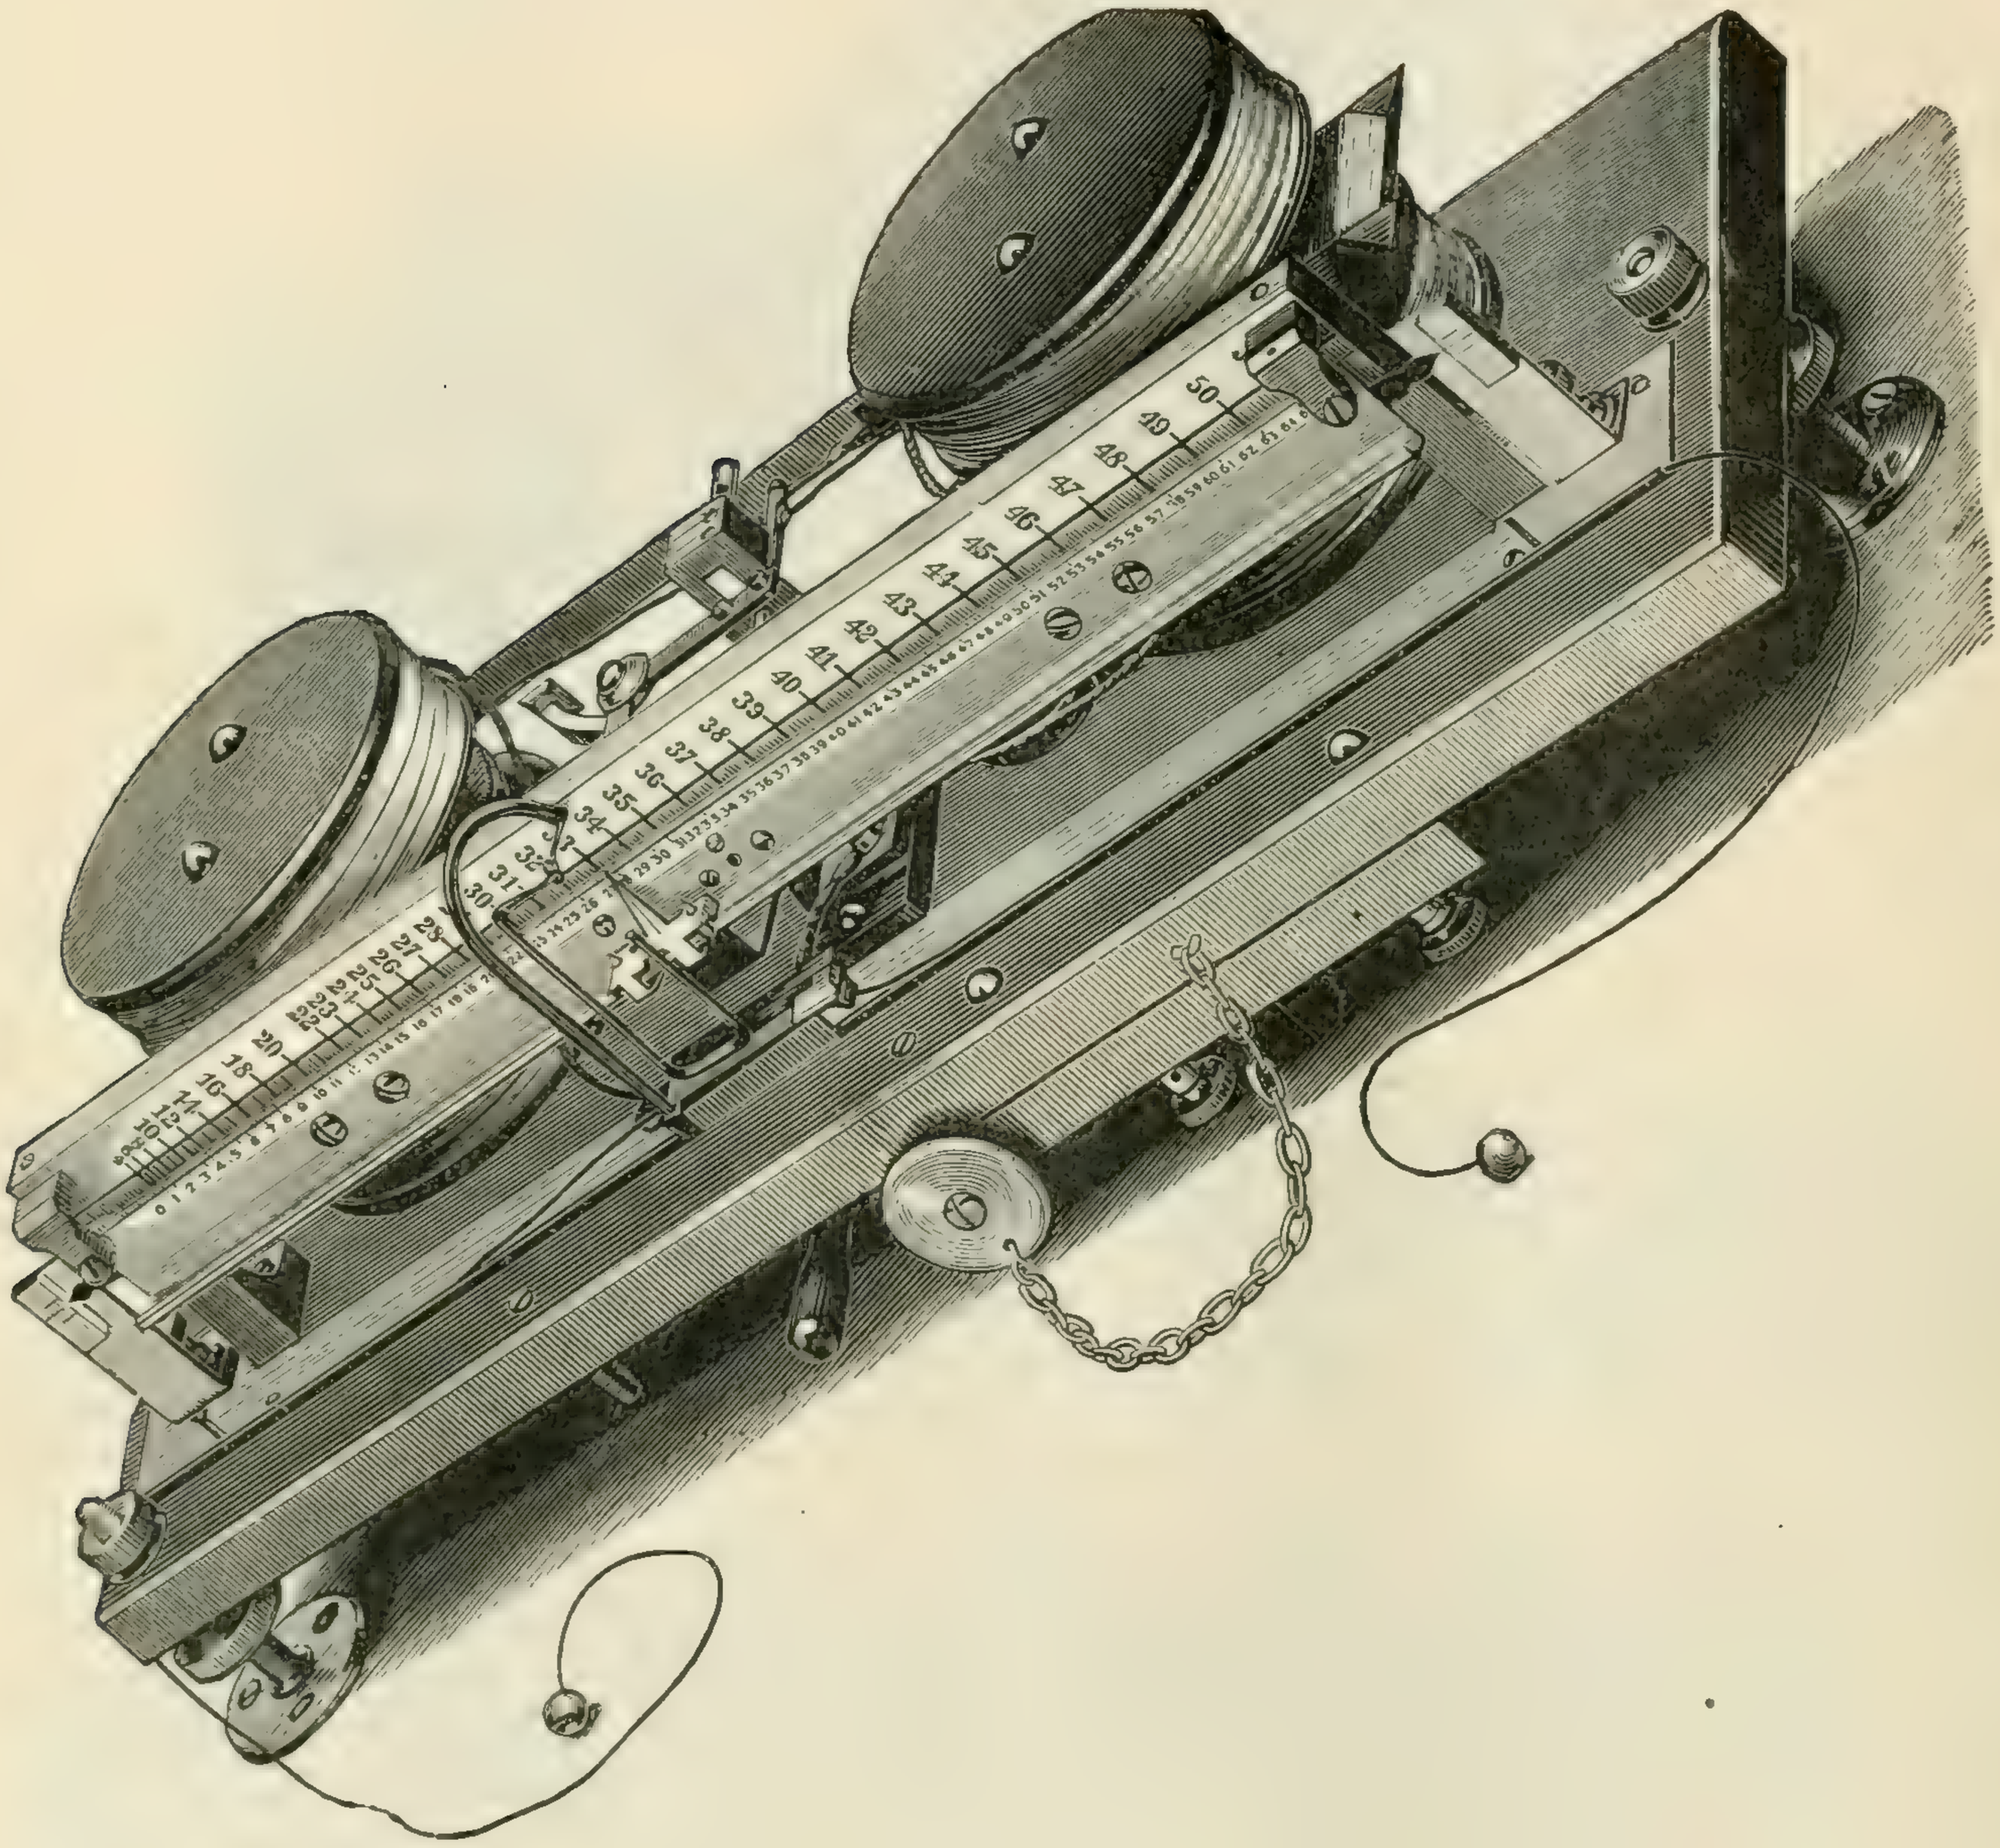
0	to	1	ampere.
1	to	5	"
5	to	25	"
25	to	125	"



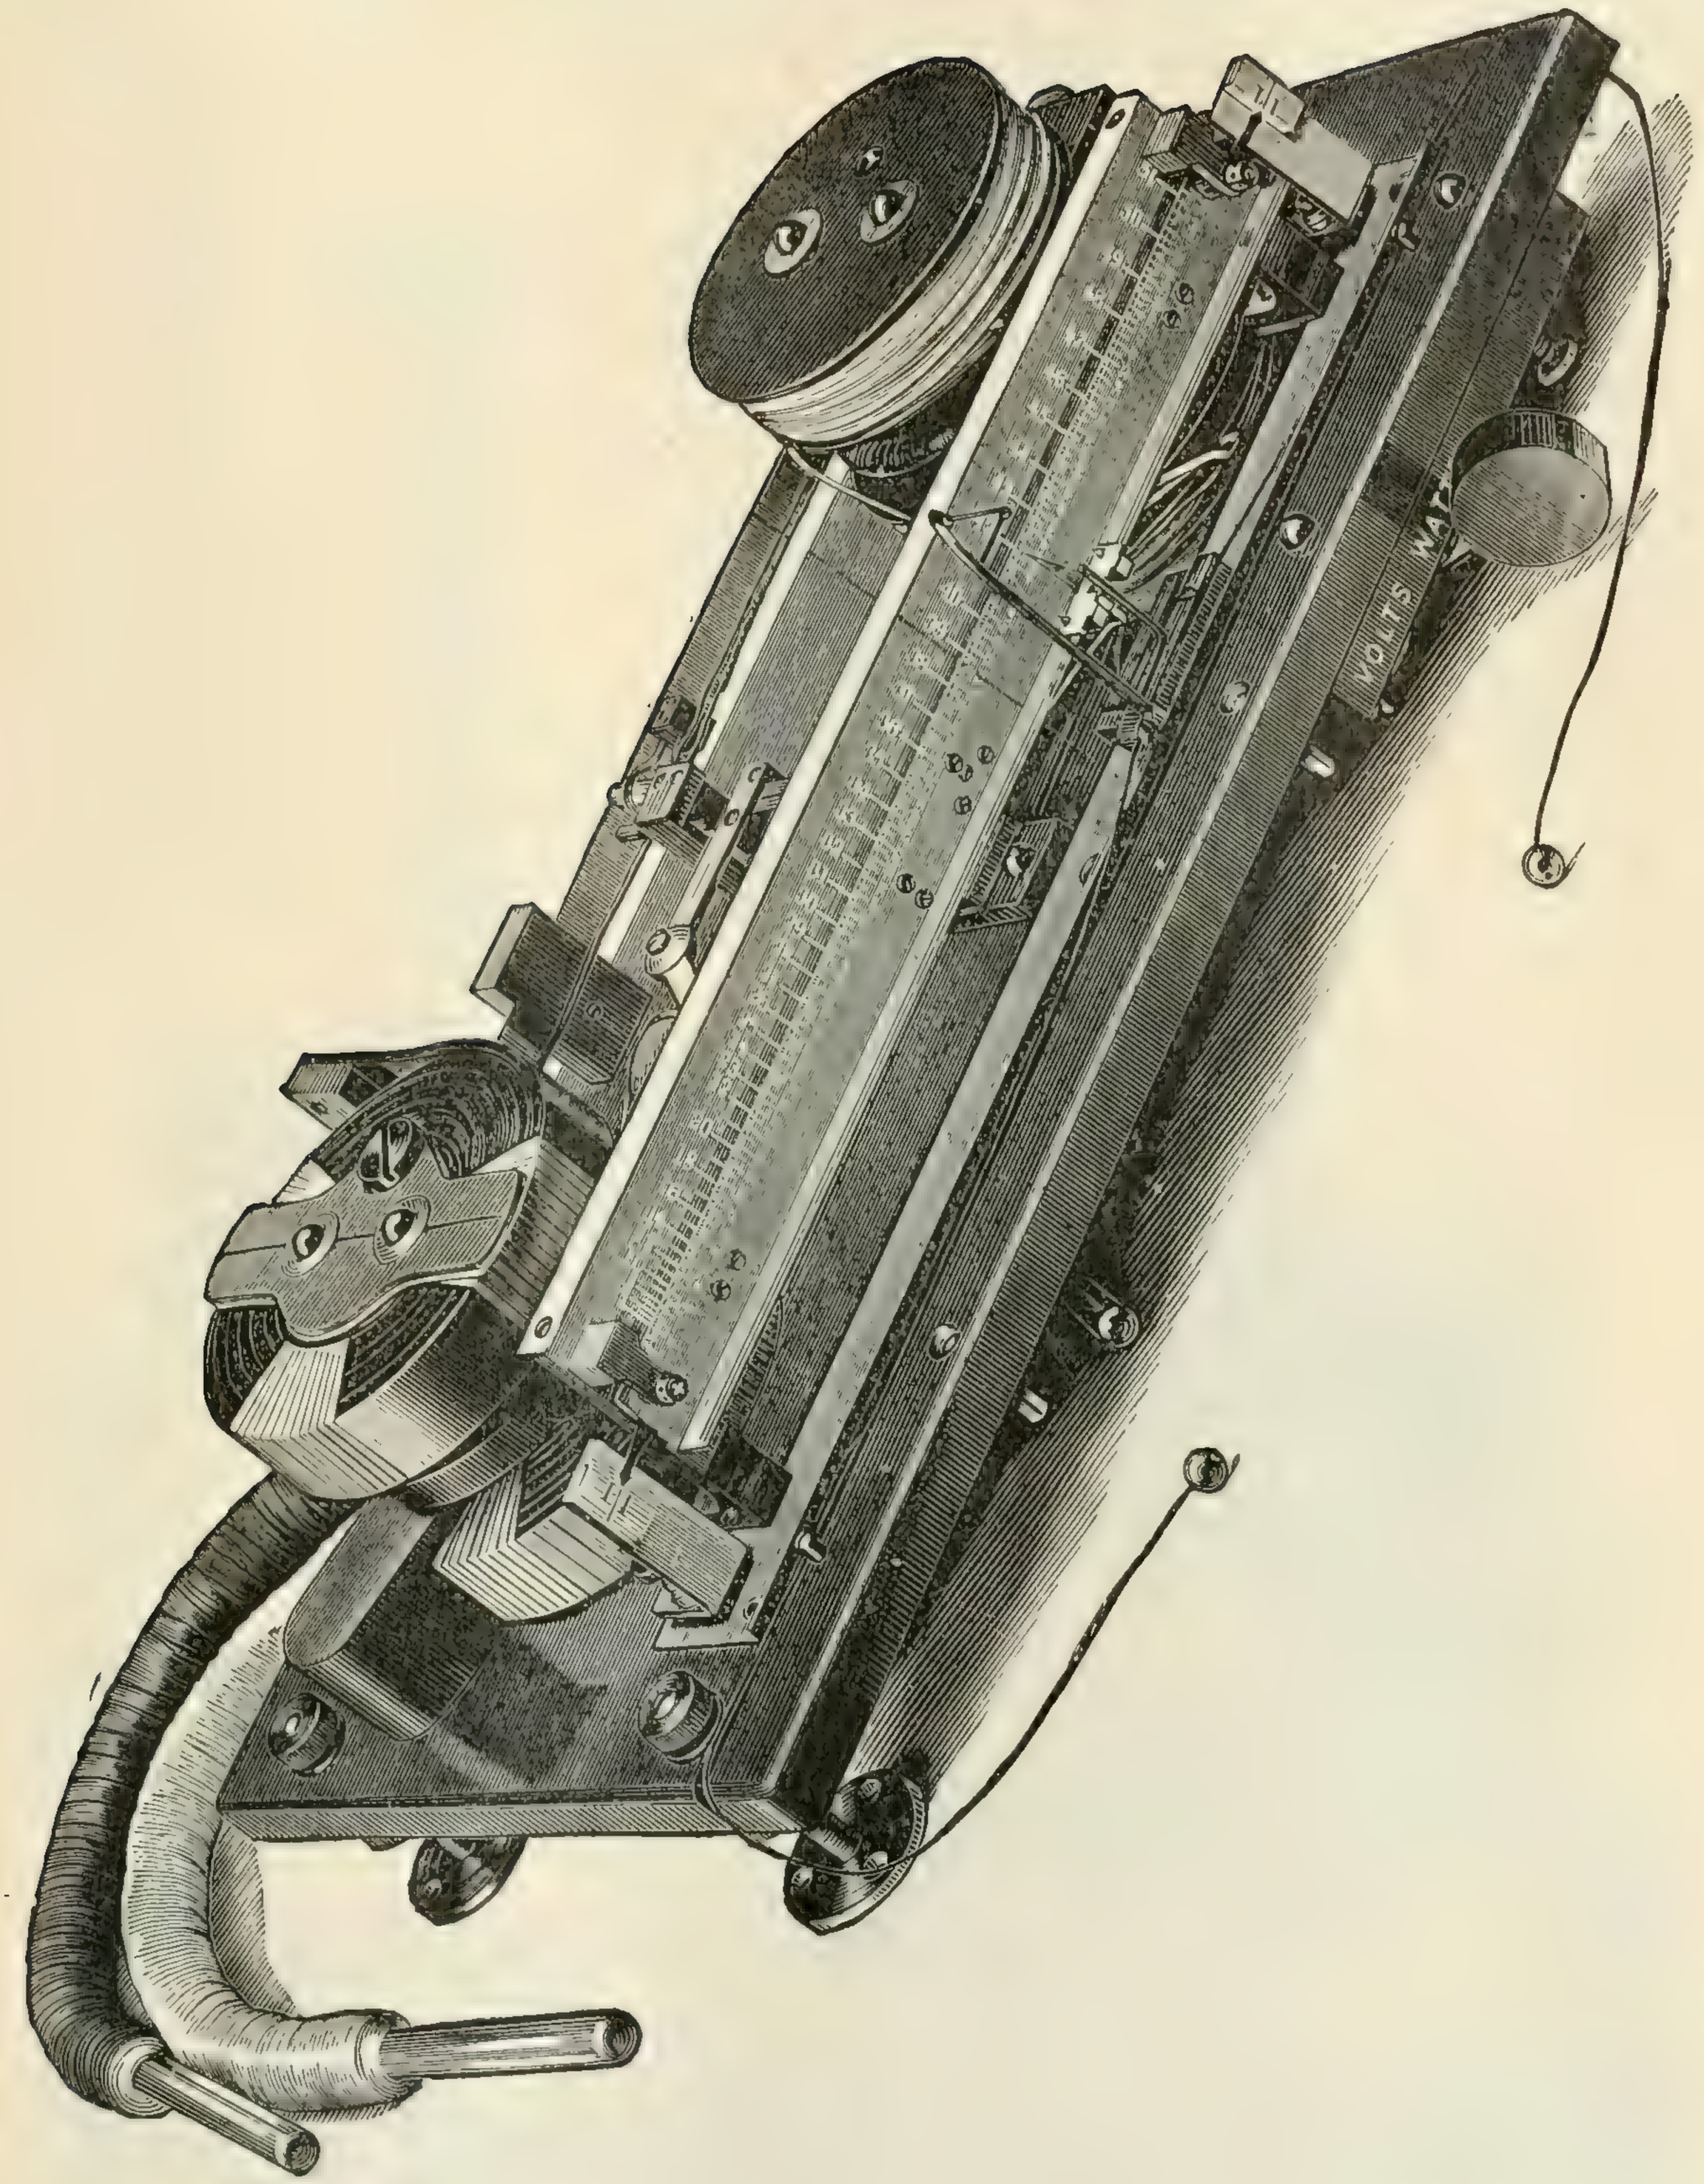
These instruments are founded on the mutal forces, discovered by Ampere, between movable and fixed portions of an electric circuit. The shape chosen for the mutually influencing portions is circular and are called by Lord Kelvin 'Ampere Rings'. In each of the instruments each movable ring is actuated by two fixed rings, all three approxi nately horizontal. There are two such groups of three rings—two movable rings attached to the two ends of a horizontal balance arm pulled, one up and the other down by a pair of fixed rings in its neighbourhood. The current is in opposite directions in the movable rings to practically annul disturbances due to horizontal components of terrestrial or local magnetic forces. It is fortunate that these magnetic disturbances have been thus annulled for reasons that will be alluded to presently. In all of the balances the current goes in opposite directions through the two fixed rings, so that the movable ring is attracted by one of the fixed rings and repelled by the other. The balances were constructed specially for the department and are a modification of the ordinary type. They are intended as ultimate standards, great accuracy and permanency being guaranteed. The scale and sliding weights are taken away and the beam is made specially strong and has a pointer at each end. A scale pan is hung at each end of the beam, and the distance from coil to coil is greater than in the ordinary balance. The method of making an observation is by placing a weight of fixed amount on the left hand scale pan, and the beam is balanced with no current through the coils; the weight is then lifted to the right hand scale pan and the current turned on. The amount of current passing is adjusted till the beam again balances, when the current will be according to the value of the weight used. Tests, having an accuracy of $\frac{1}{2}\frac{1}{0}$ of 1 per cent can be quickly made, and with more careful manipulation, a much higher degree of accuracy can be attained.

For purposes of graduation or standardization, the silver voltameter is used. It is one of the most accurate for calibrating current measuring instruments. It depends on the well-known principle that when a current of electricity flows through an electrolyte, the amount of decomposition resulting in a given time is directly proportional to the

total quantity of electricity which has passed in that time. For any substance 1 coulomb will always decompose or liberate at the cathode the same fixed weight of the substance and is defined as its electro-chemical equivalent. The latest experiments agree in giving 0·001118 (9,634 C.G.S. units) as the electro-chemical equivalent of silver. The specification for the electrolyte is given in schedule B. A more convenient, if not



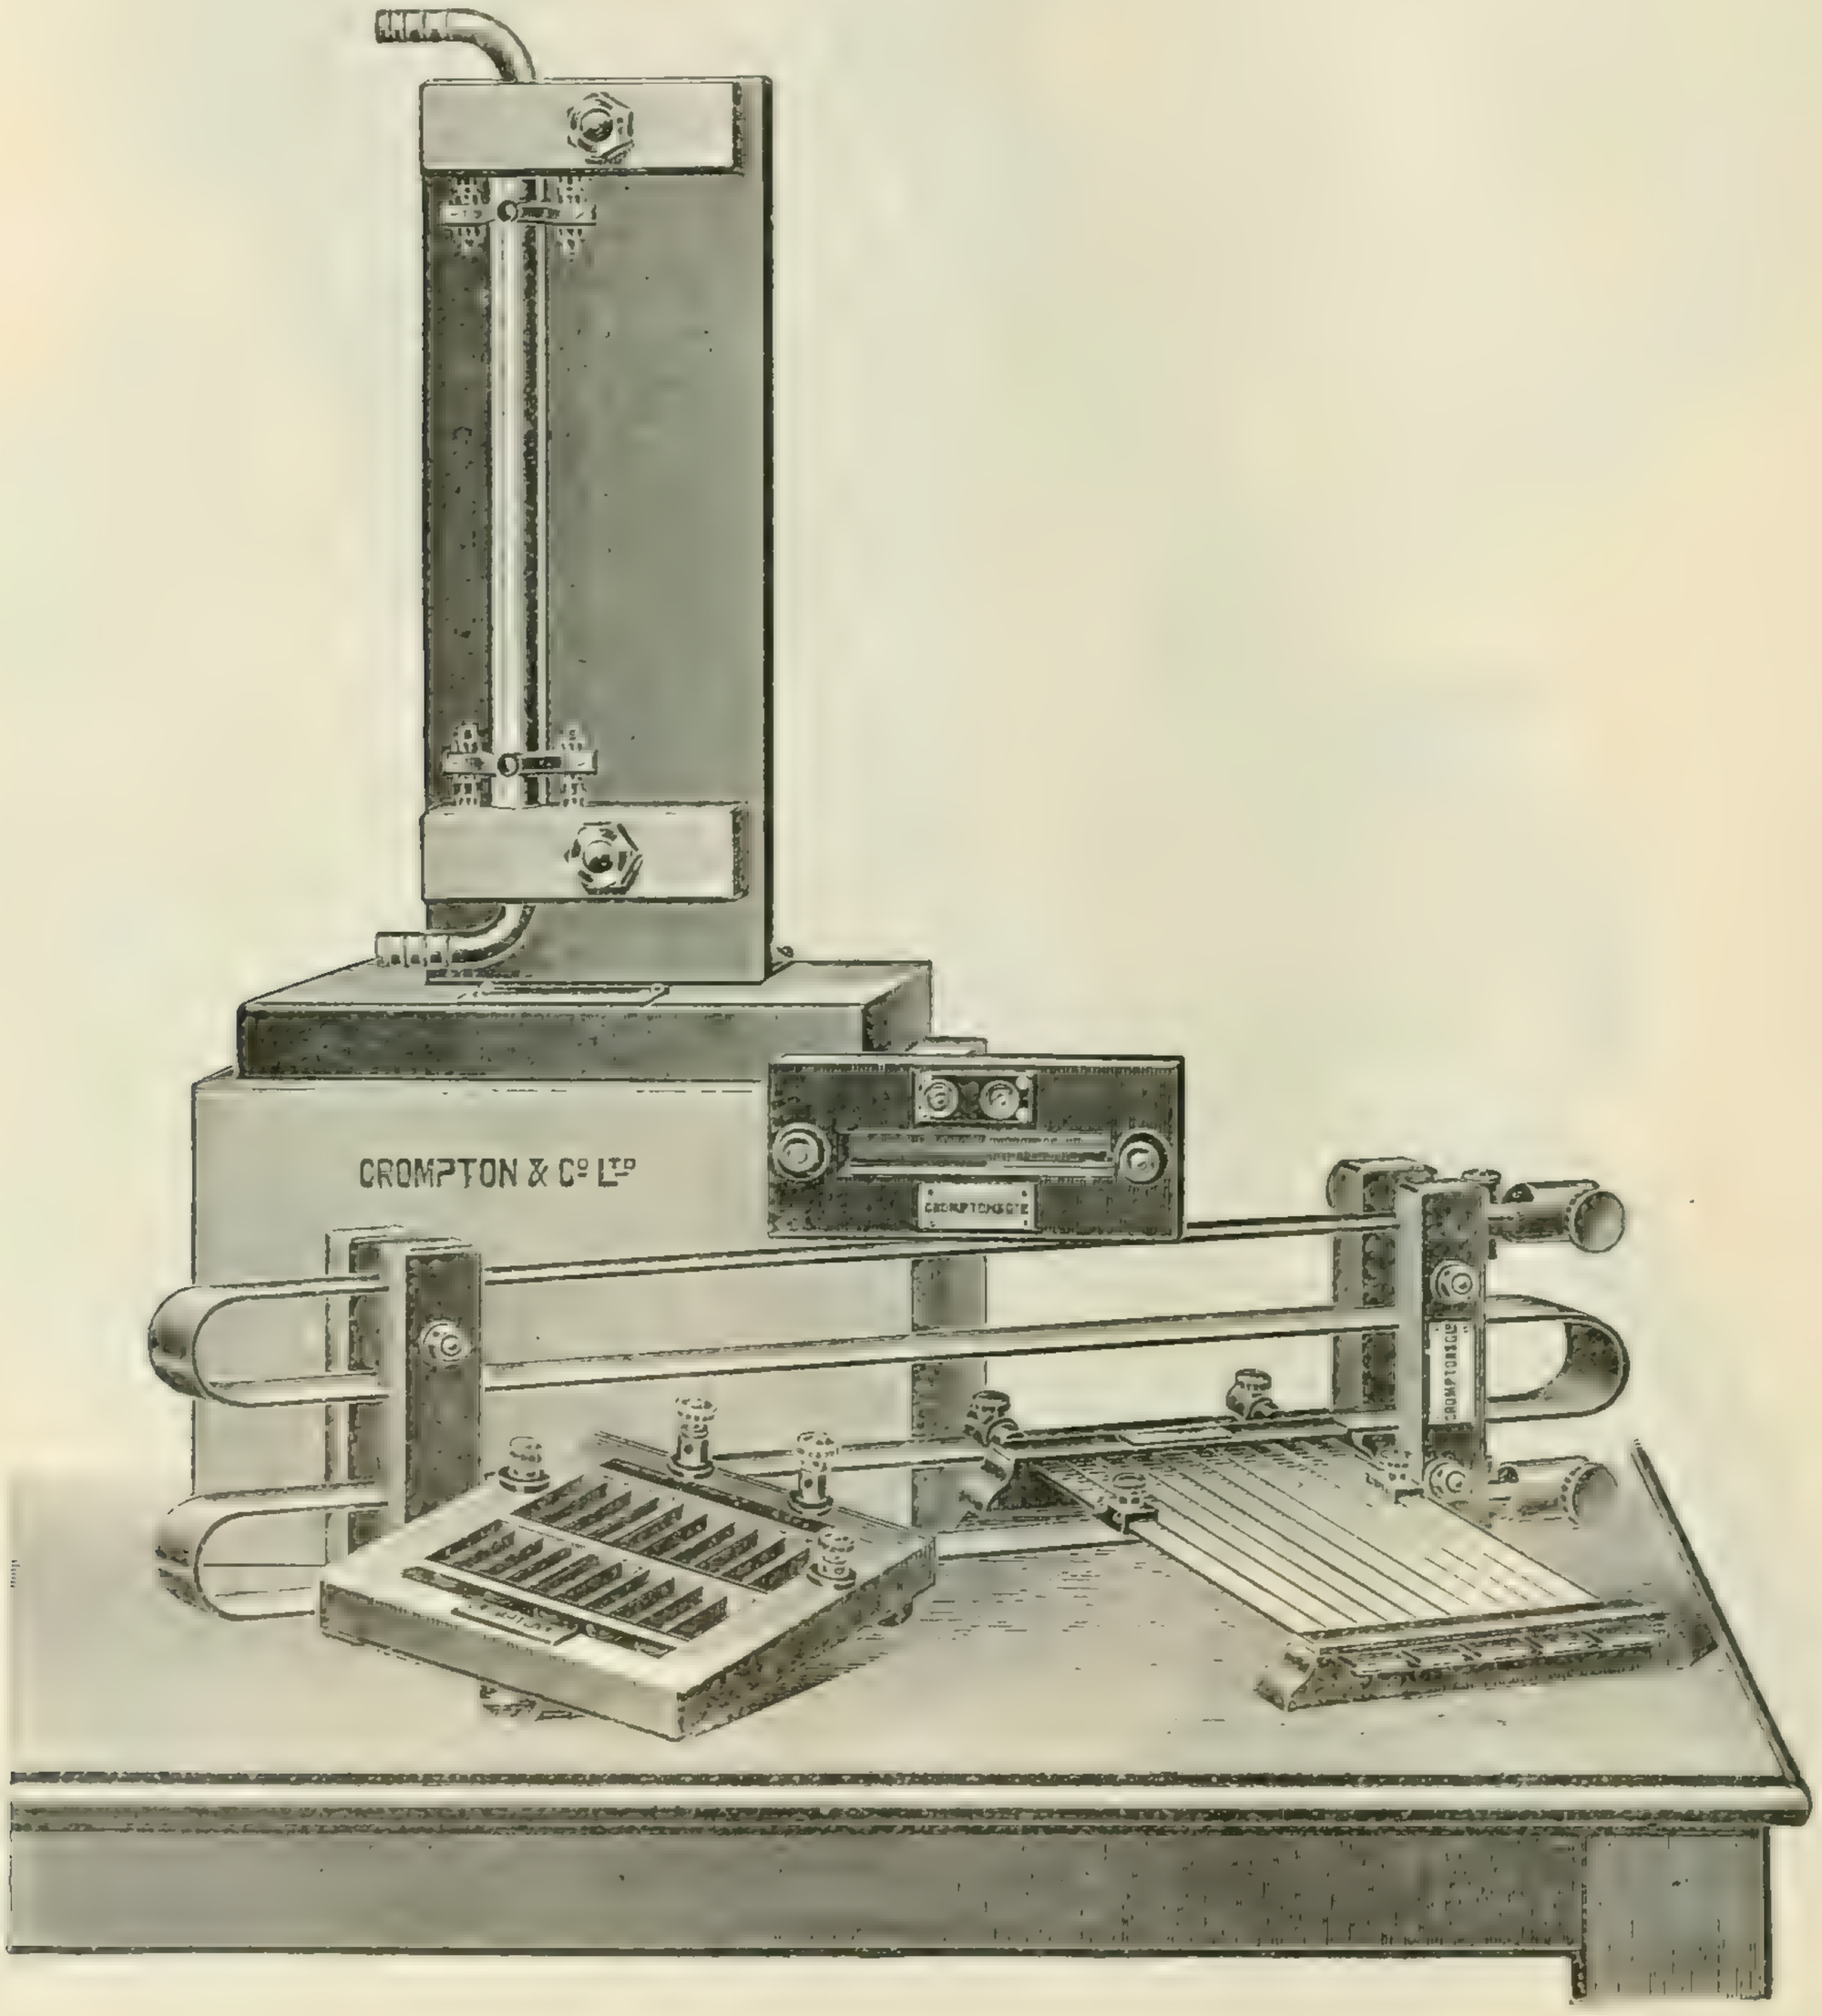
quite as accurate a method is the copper cell. The exerimenter should be careful to procure pure copper sulphate and plates and the use of a chemical balance. A small quanti y of sulphuric acid will improve the electrolyte. The electro-chemical equivalent of copper is 0·00337 or 1·177 grammes of copper are deposited per ampere hour, approximately.



VOLTS
WATTS

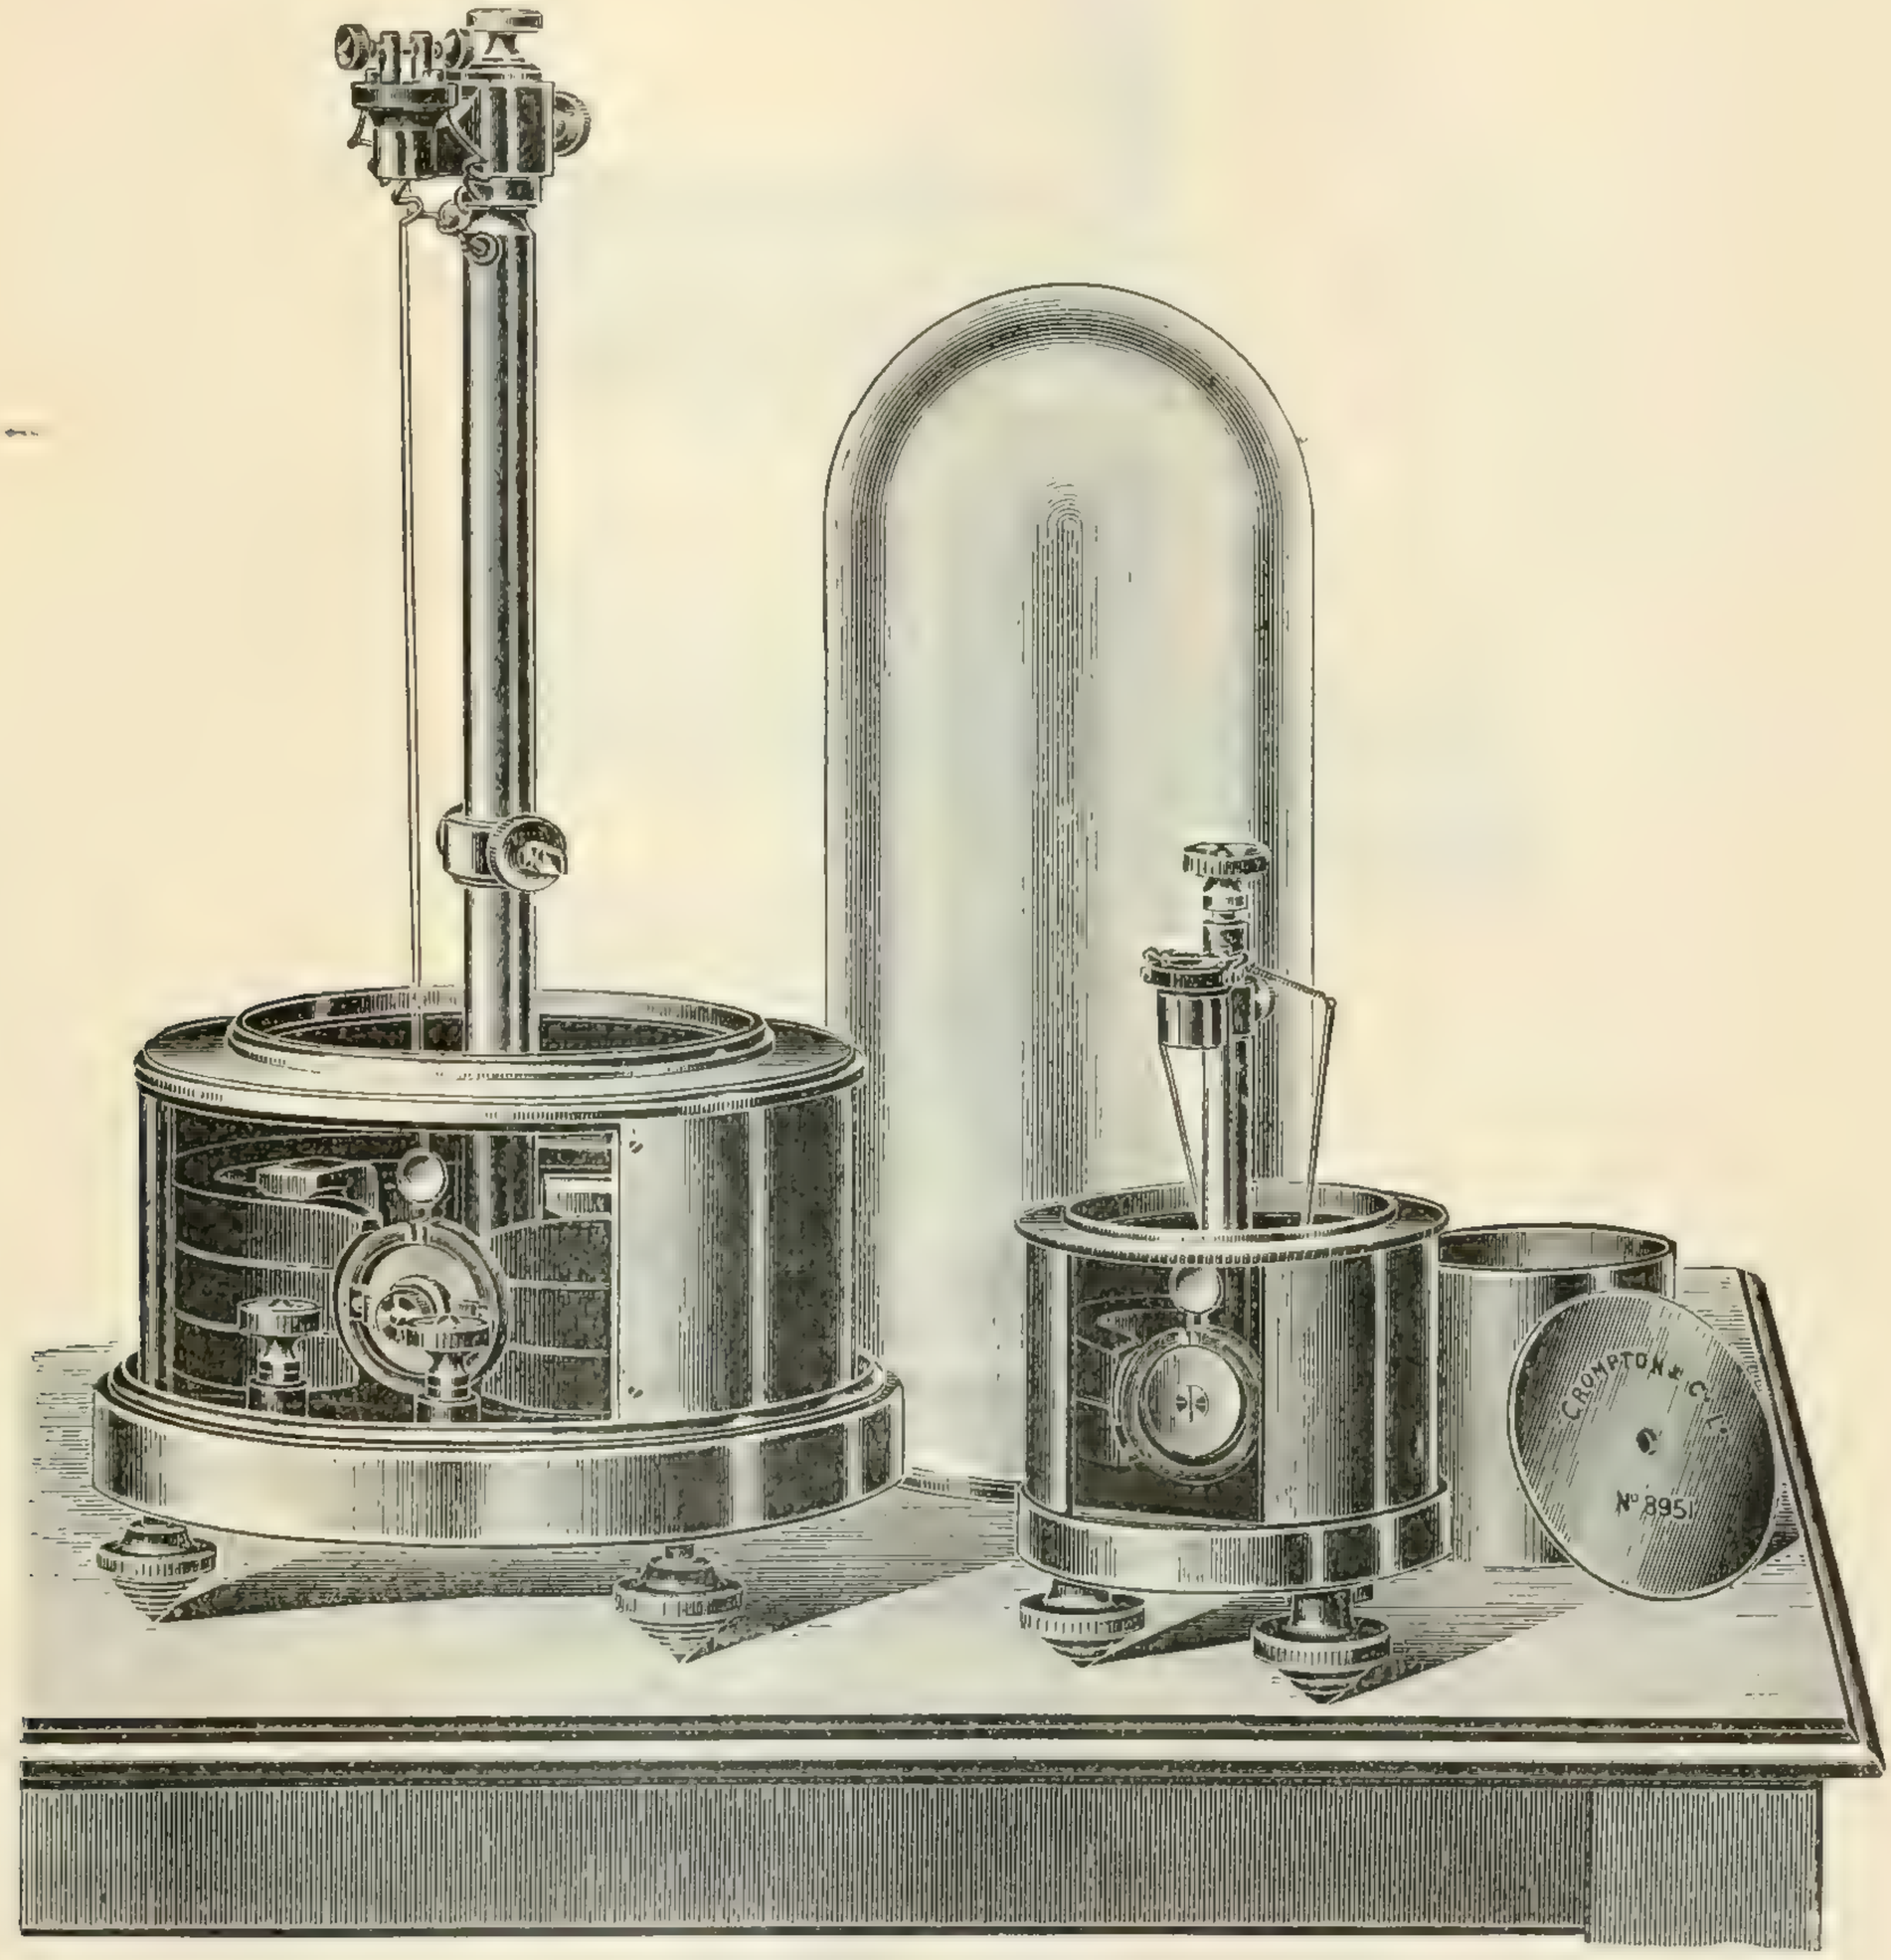
Another method for the measurement of current and the standardization of instruments is the fall of potential or potentiometer method. The department is now installing one of Crompton's laboratory instruments of this type, made expressly to order and suitable for reproducing and comparing standards with the highest possible degree of accuracy. Standard resistances of the following capacity are furnished with the instrument for current measurement :—

Resistance in ohms.	Maximum current in amperes.
1.	1.5
.5	3.
.1	15.
.01	150.
.005	300.



These resistances consist of a sheet or strip of metal, or a coil of wire, each provided with four terminals, two for connection to the circuit and two for connection to the potential leads. The resistances are made of manganin and owing to the exceedingly low temperature co-efficient of the alloy, no temperature correction is necessary except for accuracies exceeding 1 part in 1,000 when a curve giving the temperature value of the

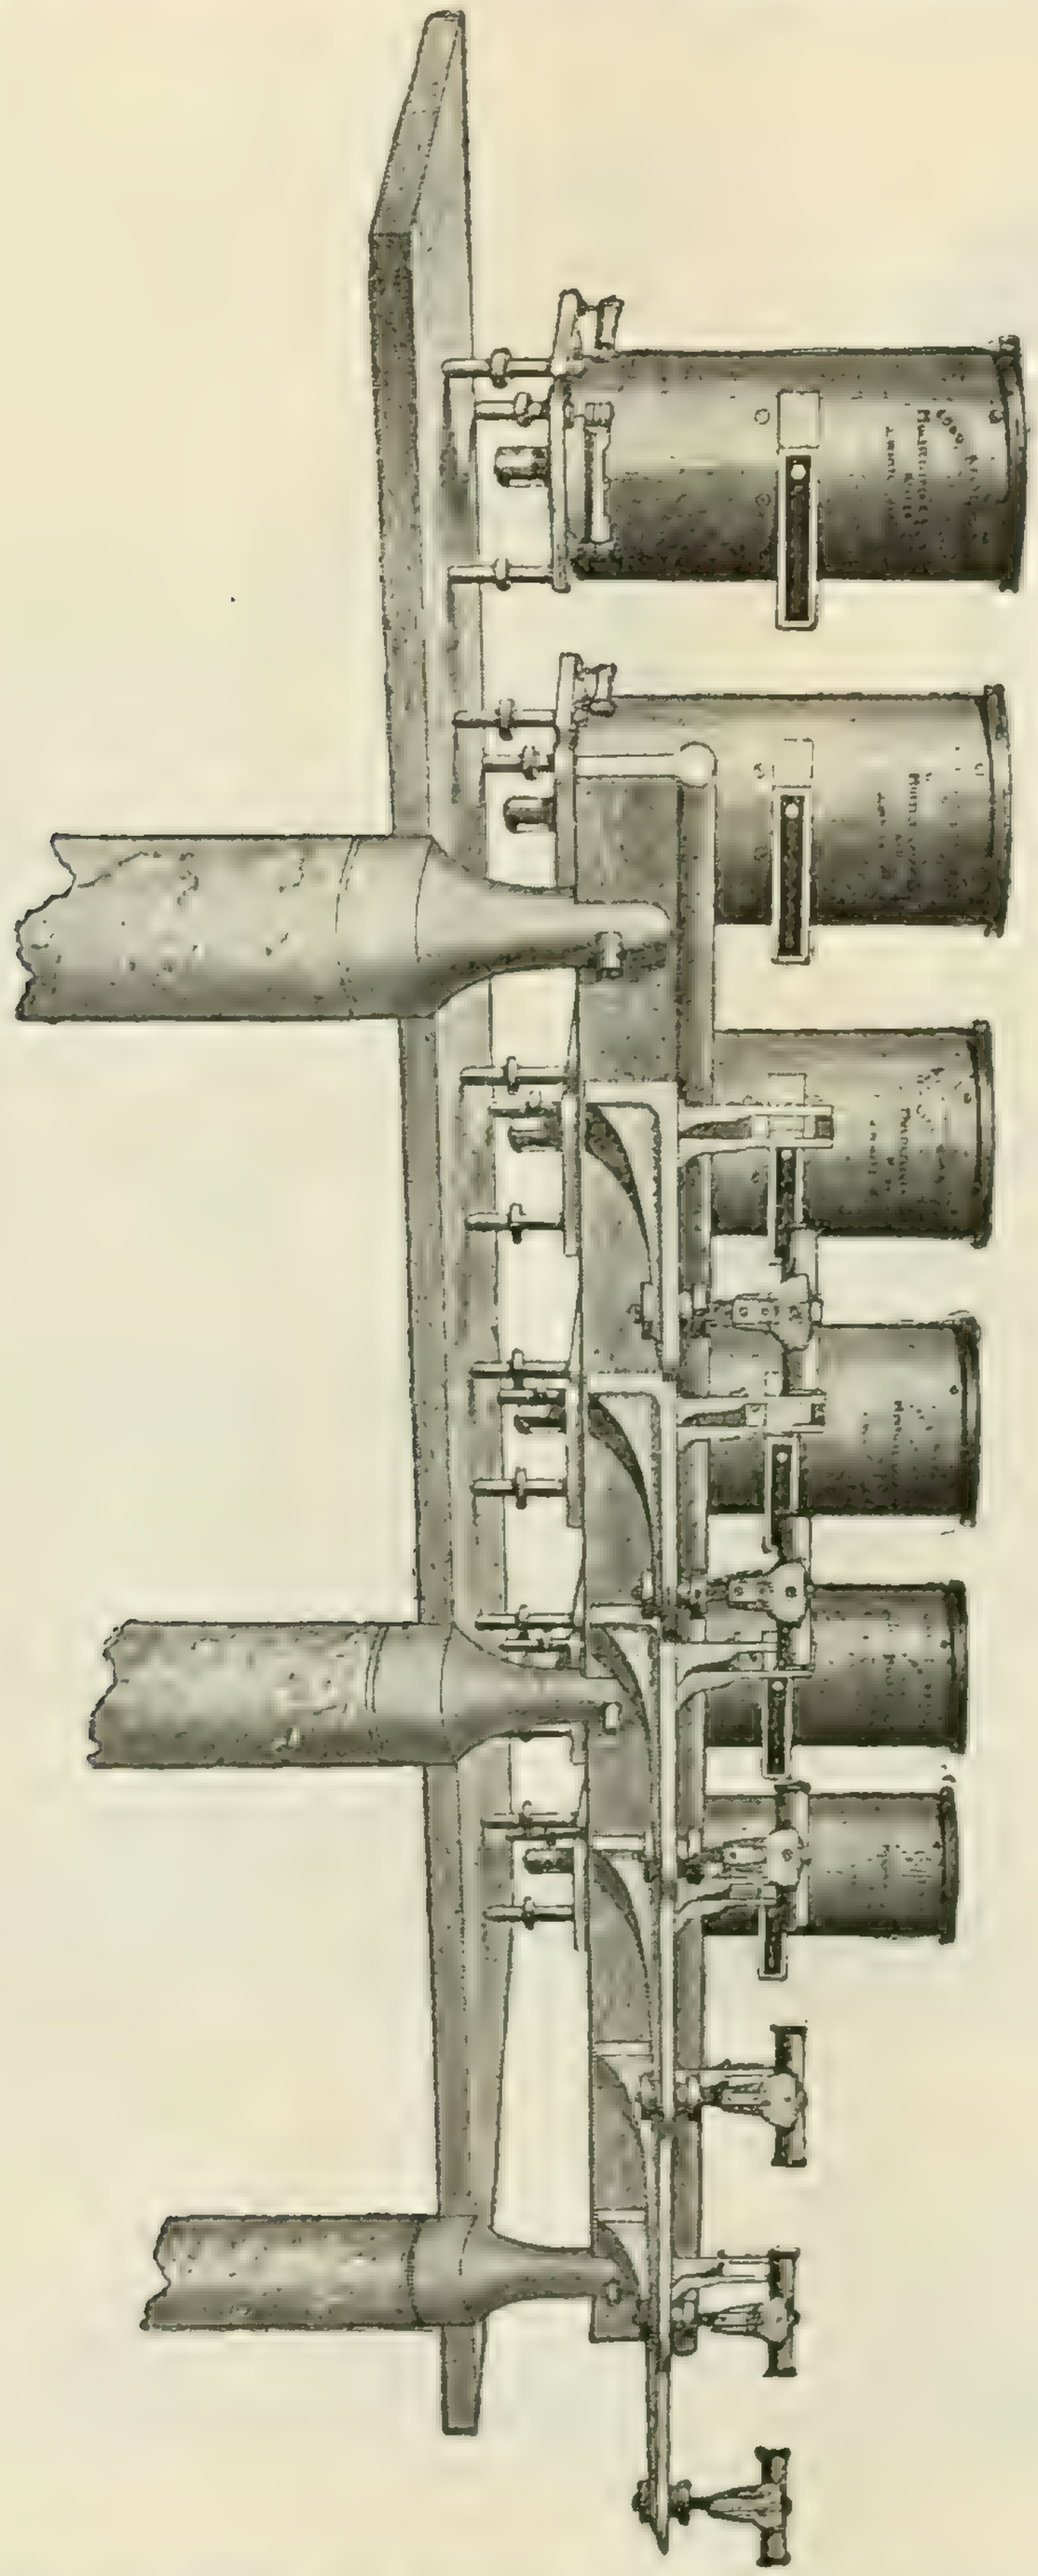
whole range of current that the instrument is capable of carrying is supplied. The current to be measured is passed through one ef these standard resistances and the fall of potential noted. If the resistance standards are properly proportioned to the instrument, the reading in amperes will be direct. Thus a standard carrying 1,500 amperes should cause a fall of 1·5 volts, each section of the instrument being equivalent to $\frac{1}{10}$ of a volt will therefore correspond to 100 amperes. The accuracy of the apparatus for current measurement, as will be observed, is largely dependent on the accuracy with which the standard resistances are constructed.



Another and similar method for the measurement of current by the fall of potential is that known as the "Vienna method." A set of instruments comprising a Weston milli-voltmeter and shunt box have been procured and forms one of the most flexible, and at the same time, accurate means of current measurement. In this as in the preceding method, if the resistances are proportional to the voltmeter, the reading in amperes will be direct. The resistances in the shunt box are made of manganin alloy with practically no temperature variation and are correct to $\frac{1}{5}$ of 1 per cent. The combination gives three full scale readings as follows:— From 0 to 1.5 ampere, from 0 to 15 amperes, and from 0 to 150 amperes. Tests can be made with great rapidity and readings on each scale from a small fraction of an ampere up to 150 amperes can be had in the space of two or three minutes.

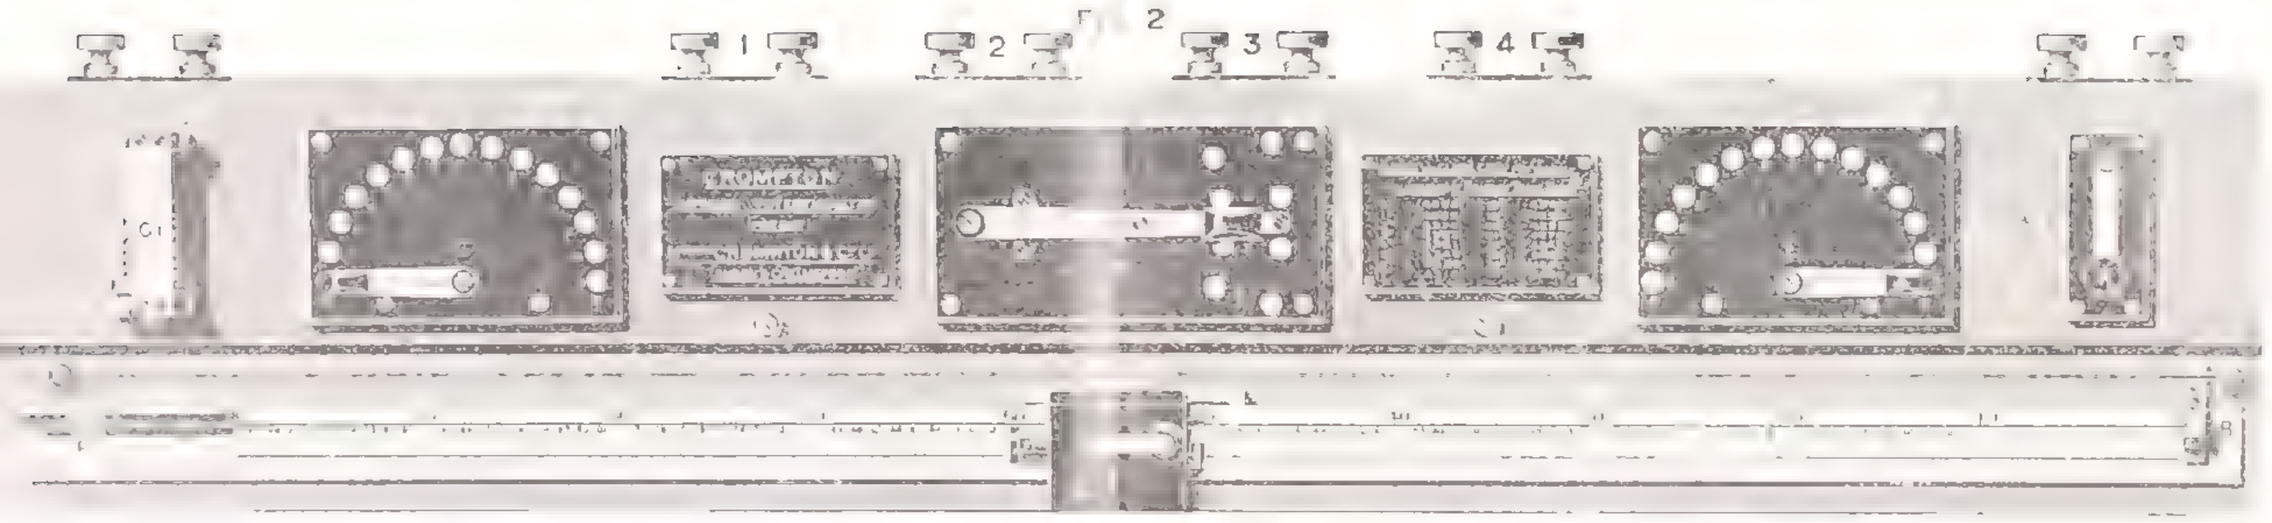
MEASUREMENT OF ELECTRO-MOTIVE FORCE.

Primary Standards.—Two standard Clark cells; three Hibbard 1 volt cells and a set of six special standard multicellular electrostatic voltmeters by Lord Kelvin. The latter covers a range of from 20 to 3,200 volts and was specially constructed for the department as ultimate standards of E.M.F. great accuracy and permanency, being guaranteed. During the two years since the instruments were first installed, the



variation in the calibrating curves has been less than 1 part in 10,000. These instruments have the great advantage of being equally accurate on direct or alternating circuits. Being electro-static, they use no current and are unaffected by local magnetic conditions. They can be kept continuously in circuit and require no temperature correction.

The instruments are calibrated by comparison with the difference of potential between the terminals of a known resistance through which the current is being



1
2
2
3
4

measured by means of a Kelvin standard centi-ampere balance, or by the potentiometer method.

Inter-comparisons with the standard e.m.f. cells are periodically made and all variations recorded. The method of comparison followed is that known as the Clark-Poggendorff method and consists in the balancing of electro-motive forces against one another by the changing of resistances. It is preferred over most other methods for the reason that it is both a *zero* and *null* method. The apparatus used comprise a sensitive galvanometer, two or three cells of working battery, the E. M. Fs. E_1 and E_2 to be compared and adjustable high resistances r_1 and r_2. Different readings of resistances are made and a comparison of the E. M. F. obtained from the relation :—

$$E_1 : E_2 = r_1 : r_2.$$

The specification for the standard Clark cell will be found in Schedule C.

THE POTENTIOMETER.

This excellent piece of laboratory apparatus and its adjuncts, though equally applicable to the measurement of current and resistance more properly comes under the head of E. M. F. standards for treatment. The fall of potential method of making measurements originated with Poggendorf, but the credit for developing the system from a crude workshop method up to what may fairly be described as a scientific instrument of no mean calibre, mainly belongs to Col. R. E. Crompton, of London. Measurements from the lowest to the highest value may be taken by direct comparison with the legal standard, to well within $\frac{1}{10}$ of one per cent under ordinary circumstances, whilst by special care a far higher degree of accuracy may be attained.

The form of instrument now being furnished the department by the Messrs Crompton may be said to consist of 15 sections of wire connected in series, 14 of which are in the form of coils within the instrument, the 15th being stretched along a scale suitably divided ; they are accurately adjusted with each other, so that with a fixed e. m. f. of 1·5 volts over the whole, each section has a fall of $\frac{1}{10}$ of a volt, the scale beneath the slide wire having 1,000 divisions, each corresponding therefore, to $\frac{1}{10000}$ of a volt. The unknown quantity to be measured is placed in series with a galvanometer attached to the movable contacts on the slide wire and is so connected up that its e. m. f. opposes that of the main circuit of the instrument. No deflection of the galvanometer takes place when the point of balance between the opposing e. m. f's. is obtained. The value of the comparison is then read from the scale. The instrument is calibrated by substituting for x a known value or standard—in this case a standard Clarke's cell—its temperature noted, and the contacts on the slide wire placed upon the figures corresponding with the value of the cell which would be 1.434 or 14 and 34. Resistance is added in the main circuit until there is no deflection on the galvanometer due to the fact of the e. m. f's. in the main and galvanometer circuits being equal ; the instrument is thus standardized from what afterwards becomes the x circuit and is then ready for obtaining the value of unknown e. m. f's. Multiples and submultiples of the ohm are used to vary the range of the instrument. They are so proportioned that their maximum carrying capacity is some definite value proportional to that of the instrument (1·5 volts) and it is entirely upon them that the range of the apparatus depends. Given proper standard resistances, the range of the instrument is practically illimitable.

Weston standard voltmeters are used as secondary standards of e. m. f., both for direct and alternating current.

One of these, for alternating current work was, specially made for our laboratory and has its coils and working parts immersed in oil, thus making it absolutely *dead beat* in its operation. It is supplied with a differential scale giving readings to $\frac{1}{5}$ volt. These voltmeters are furnished with multipliers giving ranges from 0 to 1,500 volts and accurate to within $\frac{1}{10}$ of one per cent.

MEASUREMENT OF ELECTRICAL ENERGY

One Standard Kelvin Watt Balance.—This balance is intended to measure the true energy developed in an inductive alternating current circuit. It is similar in form to the Ampere Balances, but the movable coils are wound with fine wire. These coils are of low resistance and are joined up in series with a large non-inductive resistance in a potential circuit across the mains, while the fixed coils carry the whole current to be measured. Three sets of weights are supplied with the instrument weighing respectively 1·7564 grms., 4·3910 grms., and 17·5640 grms. The constant for each set of weights with 1·000 ohms in the fine wire circuit is 2 watts, 5 watts and 20 watts per division of the scale. The constants vary directly as the resistance in the fine wire circuit. This instrument has proven to be an excellent standard having been in constant use for four years with absolutely no change in its accuracy.

Secondary Watt Standards in use by the departmental officers are those of the Weston and Hoyt types.

ACCESSORIES.

The following apparatus as accessories to the foregoing standards have been installed in the department:—

One 5 Kilowatt rotary transformer 500 to 120 volts for charging storage batteries;

One 5 Kilowatt alternator 60 cycles 104 volts.

One 5 Kilowatt alternator 130 cycles 104 volts.

One 5 Kilowatt direct current motor for operating the alternators.

300 small cells of secondary battery as a source of e. m. f. for direct current pressure tests.

55 cells type E 9 chloride accumulators for operating the direct current motor.

The alternators are so constructed as to admit of wide ranges of variation both in respect of voltage and frequency.

PHOTOMETERIC MEASUREMENT OF LIGHT.

The Bunsen Photometer is used throughout the Dominion by the officers of the department. This piece of apparatus is so well known that a lengthy explanation of it before this association would be quite unnecessary. It is known as the grease spot method, and consists mainly of a wooden movable frame over which a piece of white paper is fixed with a grease spot in the centre. The two sources of light to be compared shines on either side of the disc and the practical value of the light to be measured is determined by the total brightness which that light is capable of producing on the disc when compared with the total brightness which the unit candle is capable of producing on the same surface. In order that both sides of the disc may be read simultaneously, a system of mirrors, introduced by Rudorff, is used. The sliding carriage containing this arrangement of disc and mirrors is moved along the scale until it reaches a point where the spot entirely disappears. The candle-power of the light being measured is then obtained by dividing the square of the distance of the source of light from the screen by the square of the distance of the standard candle from the screen. Notwithstanding the fact that the sperm candle is not a first-class standard, fairly accurate work can be done with it. The incandescent lamp is now more or less used as a secondary standard for the practical measurement of light, but the system is dependent on too many conditions being fulfilled to be accepted with any degree of confidence. Sir William Preece, among a number of others, considered that an incandescent lamp of a given type, coming from the same maker, present only insignificant differences among themselves with respect to luminous intensity and efficiency, and he was of the opinion that a very convenient standard of this kind sufficiently exact for most purposes might be obtained. The subject of photometery and light standards, however, is a large one and had better be reserved for treatment on some future occasion.

SCHEDULE A.

57-58 VICTORIA.

CHAP. 38.

An Act respecting the Units of Electrical Measure.

[*Assented to 23rd July, 1894.*]

HER Majesty, by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows :—

1. This Act may be cited as *The Electrical Units Act.* Short title.

2. The units of electrical measure for Canada shall be the following :— Units established.

(*a.*) As a unit of resistance, the ohm, which is based upon the ohm equal to 10^9 units of resistance of the centimetre-gramme-second system of electro-magnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury, at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area and of the length of 106·3 centimetres. Ohm.

(*b.*) As a unit of current, the ampere, which is one-tenth of the unit of current of the centimetre-gramme-second system of electro-magnetic units, and is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with the specification contained in schedule one to this Act, deposits silver at the rate of 0·001118 of a gramme per second. Ampere.

(*c.*) As a unit of electro-motive force, the volt, which is the electro-motive force that, steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere, and which is represented sufficiently well for practical use by $\frac{1000}{1434}$ of the electro-motive force between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of 15° centigrade and prepared in accordance with the specification contained in schedule two to this Act. Volt.

(*d.*) As a unit of quantity, the coulomb, which is the quantity of electricity transferred by a current of one ampere in one second. Coulomb

(*e.*) As a unit of capacity, the farad, which is the capacity of a condenser charged to a potential of one volt by one coulomb. Farad.

Joule. (*f.*) As a unit of work, the joule, which is equal to 10^7 units of work in the centimetre-gramme-second system, and is represented sufficiently well for practical use by the energy expended in one second by one ampere in one ohm.

Watt. (*g.*) As a unit of power, the watt, which is equal to 10^7 units of power in the centimetre-gramme-second system, and is represented sufficiently well for practical use by the work done at the rate of one joule per second.

Henry. (*h.*) As the unit of induction, the henry, which is the induction in a circuit when the electro-motive force induced in that circuit is one volt, while the inducing current varies at the rate of one ampere per second.

Units and apparatus to be in Department of Inand Revenue.

3. The units of electrical measure described in the next preceding section, or such standard apparatus as is necessary to produce them, shall be deposited in the Department of Inland Revenue and shall form part of the system of standards of measure and weight established by *The Weights and Measures Act.*

SCHEDULE B.

In the following specification, the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment; and by noting this time, the time-average of the current, or, if the current has been kept constant, the current itself, can be deduced.

In employing the silver voltameter to measure currents of about one ampere, the following arrangements should be adopted. The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 centimetres in diameter and from 4 to 5 centimetres in depth. The anode should be a plate of pure silver 30 square centimetres in area and 2 or 3 millimetres in thickness. This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

The liquid should consist of a neutral solution of pure silver nitrate containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

SCHEDULE C.

The cell consists of zinc and mercury in a saturated solution of zinc suiphate and mercurous sulphate in water, prepared with mercurous sulphate in excess, and is conveniently contained in a cylindrical glass vessel.

The mercury.—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled *in vacuo*.

The zinc.—Take a portion of a rod of pure re-distilled zinc, solder to one end a piece of copper wire, clean the whole with glass paper, carefully removing any loose pieces of the zinc. Just before making up the cell, dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

The zinc sulphate solution.—Prepare a saturated solution of pure ("pure re-crystallized") zinc sulphate by mixing in a flask distilled water with nearly twice its weight of crystals of pure zinc sulphate, and adding zinc oxide in the proportion of about 2 per cent by weight of the zinc sulphate crystals to neutralize any free acid. The crystals should be dissolved with the aid of gentle heat, but the temperature to which the solution is raised should not exceed 30° C. Mercurous sulphate treated as hereinafter described, should be added in the proportion of about 12 per cent by weight of the zinc sulphate crystals, and the solution filtered, while still warm, into a stock bottle. Crystals should form as it cools.

The mercurous sulphate.—Take mercurous sulphate, purchased as pure, and wash it thoroughly with cold distilled water by agitation in a bottle; drain off the water, and repeat the process at least twice. After the last washing, drain off as much of the water as possible.

Mix the washed mercurous sulphate with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle to ensure saturation, and a small quantity of pure mercury. Shake these up well together to form a paste of the consistence of cream. Heat the paste, but not above a temperature of 30° C. Keep the paste for an hour at this temperature, agitating it from time to time; then allow it to cool, continuing to shake it occasionally while cooling. Crystals of zinc sulphate should then be distinctly visible, and should be distributed throughout the mass. If this is not the case, add more crystals from the stock bottle, and repeat the whole process. This method ensures the formation of a saturated solution of zinc and mercurous sulphates in water.

Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed in a glass tube. The ends of the wire project from the ends of the tube; one end forms the terminal; the other end and a portion of the glass tube dip into the mercury.
